

Alert Disposition & Tuning Tracker

Completed examples showing analyst judgment and detection improvement

Alert ID	Detection	Disposition	Reason	Tuning / follow-up
SOC-201	Brute Force	TP - Escalated	Failure burst followed by password-only success from unfamiliar source.	Increase priority when success follows threshold; correlate MFA/device.
SOC-202	Password Spray	TP - Contained	Multiple users targeted from one external source; no approved testing.	Keep distinct-user threshold; suppress only validated scanner ranges.
SOC-203	Impossible Travel	Benign Positive	Corporate VPN egress changed geolocation while same managed device and MFA remained consistent.	Add approved VPN ranges/device trust to enrichment; do not disable rule.
SOC-204	PowerShell	Benign Positive	Signed enterprise deployment script launched by approved management agent.	Allowlist signed script hash/path + approved parent process; keep encoded command monitoring.
SOC-205	Failed Logins	False Positive	Service account retry loop caused by stale password in scheduled job.	Route service accounts to separate rule; alert on failure volume + owner metadata.
SOC-206	Credential Stuffing	TP - Escalated	Multiple users targeted and one success occurred from same source.	Maintain high severity when any success is present.
SOC-207	Phishing URL	Informational	URL blocked before delivery and no recipients clicked.	Retain campaign telemetry; no user action needed.
SOC-208	Impossible Travel	TP - Escalated	Unknown device, password-only login, no VPN explanation, abnormal geography.	Weight device/auth-method context to reduce geo-only noise.

Tuning Principles

- Do not tune solely to reduce alert count; tune to improve signal quality without removing meaningful coverage.
- Prefer contextual suppressions such as approved scanner, signed script, managed device, or known VPN range rather than broad user/IP exclusions.
- Track what evidence justified each tuning decision.
- Retest detections after changes using both malicious-like and benign test cases.
- Monitor disposition rates over time; a sustained high false-positive rate is a rule-quality problem, not an analyst productivity problem.
